Technical Field This disclosure generally relates to computer systems, and more specifically relates to system calls for operating system components. 2. Background Art Computer systems have evolved into extremely sophisticated devices, and computer systems may be found in many different settings. Computer systems typically include a system processor and associated volatile and non-volatile memory, as well as non-transient data storage devices that allow a computer system to store and retrieve data. Non-transient data storage devices include, for example, magnetic disk drives, optical disk drives, magnetic tape drives, flash

memory, and others. These non-transient data storage devices are typically used to store instructions, data and other type of information, that a processor may read and write, often referred to as “user data.” A computer system may also include one or more graphics output devices, such as a cathode ray tube (CRT), a liquid crystal display (LCD), a flat panel display such as a liquid crystal on silicon display, or other types of displays. These graphics output devices may be used to display images of computer information to a user. The computer system may also include a local area network (LAN) for communicating data between various components within a computer system. The LAN typically includes a shared bus on which a shared memory may be stored. A collection of components coupled to the LAN is typically referred to as a “subsystem.” LANs typically allow for the transfer of data among various network components and share system resources, such as memory, in order to achieve a level of data exchange similar to that experienced in a stand-alone computing environment. Memory is a storage medium that allows data to be stored for access by the processor and other components. A typical memory includes a number of memory cells. Some memory cells are read-only cells that are used to store instructions and data. 82157476af
